# On a Numerical Method for Solving Fredholm - Volterra Integral Equation 

S. J. Monaquel<br>Department of Mathematics Faculty of Science King Abdul Aziz University Saudi Arabia<br>smonaquel@kau.edu.sa

#### Abstract

In this paper, the existence and uniqueness of solution of Fredholm - Volterra integral equation (F-VIE) of the first kind is considered in the space $L_{2}[-1,1] \times C(0, T), T<1$. Then, a numerical method is used to reduce this type of equation to a system of Fredholm integral equations (SFIEs). After this, Toeplitz matrix method (TMM) is used to obtain a linear algebraic system (LAS). Finally, the linear algebraic system is solved numerically, when the singular kernel takes the logarithmic form and Carleman function. The error, in each case, is calculated. [S. J. Monaquel. On a Numerical Method for Solving Fredholm - Volterra Integral Equation. J Am Sci 2012;8(8):96-101]. (ISSN: 1545-1003). http://www.jofamericanscience.org. 16

Keywords: Fredholm - Volterra integral equation, system of Fredholm integral equations, linear algebraic system, Toeplitz matrix method.

## 1. Introduction

The F- VIF of the first kind with singular kernel can be solved analytically, using the following methods: Cauchy method, orthogonal polynomial method, Potential theory method and Krein's method. The importance of $\mathbf{F}$ - VIE of the first kind and contact problem came from the work of Abdou [1]. Where, the solution of $\mathbf{F}$ - VIE of the first kind in one, two and three dimensional has been obtained, analytically using separation of variables method. Beside this, the relations between the F-VIE and contact problems in the theory of elasticity have been discussed in [2, 4]. The references [5-10] contain some different methods to obtain the solution of the singular integral equations numerically.
Consider the linear IE:

$$
\begin{equation*}
\phi(x, t)=f(x, t)+\lambda \int_{-1}^{1} k(x, y) \phi(y, t) d y+\lambda \int_{0}^{t} F(t, \tau) \phi(x, \tau) d \tau \tag{1}
\end{equation*}
$$

The linear IE (1) is called $\mathbf{F}$ - VIE of the second kind, in the space $L_{2}[-1,1] \times C[0, T], T<1$. In Eq. (1), the FI term is considered in position and its kernel $k(x, y)$ has a singular term. While the VI term is considered in time and its kernel $F(t, \tau)$ is positive and continuous for all $t, \tau \in[0, T], T<1$.
In order to guarantee the existence of a unique solution of Eq. (1), we assume the following conditions:
(i) The kernel $k(x, y)$ satisfies the discontinuity condition:

$$
\left[\int_{-1}^{1} \int_{-1}^{1}|k(x, y)|^{2} d y d x\right]^{\frac{1}{2}}=c<\infty \quad, \quad(c \text { is a constan} \theta)
$$

(ii) The kernel $F(t, \tau) \in C(\lfloor 0, T \mid \times\lfloor 0, T]), 0 \leq \tau \leq t \leq T<1$, satisfies :

$$
|F(t, \tau)| \leq M, \forall t, \tau \in[0, T], M \text { is a constant }
$$

(iii) The given function $f(x, t)$ with its partial derivatives with respect to $x$ and $t$ are continuous in $L_{2}[-1,1] \times C[0, T]$ where,

$$
\|f(x, t)\|=\max _{0 \leq \leq T} \int_{0}^{t}\left[\int_{-1}^{1}|f(x, \tau)|^{2} d x\right]^{\frac{1}{2}} d \tau=H, \quad H \text { is a constant }
$$

(iv) The unknown function $\varphi(x, t)$ satisfies Lipschitz condition with respect to position and Hölder condition with respect to time.

In this paper, the $\mathbf{F}-$ VIE of the second kind is solved numerically in the space $L_{2}[-1,1] \times C(0, T), T<1$. The kernel of FI term is considered in the logarithmic form and Carleman function with respect to position, while the kernel of VI term is considered as a positive continuous function in time. In section two, using a numerical method, the F-VIE will reduce to linear SFIEs. In section three TMM, as the best numerical methods, is discussed and applied to solve the FIE of the second kind with discontinuous kernel. In section four, numerical results are computed and the estimating error, in each case, is calculated.

## 2. The System of Fredholm Integral Equations

For representing (1) as SFIEs, we divide the interval $[0, \mathrm{~T}]$ as $0 \leq t \leq T<1$, where $0=t_{0}<t_{1}<t_{2}<\cdots<t_{k}<\cdots<t_{N}=T$, then let $t=t_{k}, \quad k=0,1,2, \cdots, N$. Using the quadrature formula, see [11-13], the VI term in (1) becomes $\int_{0}^{t_{k}} \varphi(x, \tau) F\left(t_{k}, \tau\right) d \tau=\sum_{j=0}^{k} u_{j} F\left(t_{k}, t_{j}\right) \varphi\left(x, t_{j}\right)+Q\left(\hbar_{k}^{\tilde{p}+1}\right), \quad\left(\hbar_{k} \rightarrow 0, \tilde{p}>0\right)$

Where,
$\hbar_{k}=\max _{0 \leq j \leq k} h_{j}, \quad h_{j}=t_{j+1}-t_{j}$
The values of $k$ and the constant $\widetilde{p}$ depend on the number of derivatives of the kernel of VI term $F(t, \tau)$, for all $\tau \in[0, T]$, with respect to $t$, for example if the function of time $F(t, \tau) \in C^{3}[0, T]$, then we have $\tilde{p}=3, \quad \tilde{p} \approx k$, and $u_{0}=\frac{1}{2} h_{0}$ , $u_{k}=\frac{1}{2} h_{k}, u_{i}=h_{i}, \quad(i \neq 0, k)$. Using Eq. (2) in Eq. (1), after letting $t=t_{k} \quad, k=1,2, \ldots, N$, we have
$\phi_{k}(x)=f_{k}(x)+\lambda \int_{-1}^{1} k(x, y) \phi_{k}(y) d y+\lambda \sum_{j=0}^{k} u_{j} F_{k, j} \phi_{j}(x)$

The formula (3) can be adapted in the form
$\left(1-\lambda u_{k} F_{k, k}\right) \phi_{k}(x)=f_{k}(x)+\lambda \int_{-1}^{1} k(x, y) \phi_{k}(y) d y+\lambda \sum_{j=0}^{k-1} u_{j} F_{k, j} \phi_{j}(x)$

Here, we used the following notations:
$\varphi_{k}(x)=\varphi\left(x, t_{k}\right), f_{k}(x)=f\left(x, t_{k}\right), F_{k, j}=F\left(t_{k}, t_{j}\right)$
The formula (4) represents SFIEs. In this aim, we write (4) in the form
$\mu_{n} \phi_{n}(x)=G_{n}(x)+\lambda \int_{-1}^{1} k(x, y) \phi_{n}(y) d y$
where $\mu_{n}=\left(1-\lambda u_{n} F_{n, n}\right)$, and
$G_{n}(x)=f_{n}(x)+\lambda \sum_{j=0}^{n-1} u_{j} F_{n, j} \varphi_{j}(x), n=0,1,2, \cdots, N$.
The formula (5) leads to say that, we have $N$ unknown functions $\varphi_{n}(x)$ corresponding to the time interval $[0, T], \mathrm{T}<1$. In addition, for all values $\mu_{n}=$ constant $\neq 0$, we have SFIEs of the second kind, while for all values $\mu_{n}=0$, we have the integral system of the first kind.

## 3. The Toeplitz Matrix Method, see [9, 14]

Here, in this section we present TMM, as the best numerical method for solving the singular integral equations, to obtain numerically the solution of FIE of the second kind with singular kernel. The idea of this method is to obtain a system of $2 N+1$ linear algebraic equations, where $2 N+1$ is the number of the discretization points used.
In this aim, consider the FIE of the second kind:

$$
\begin{equation*}
\phi(x)-\lambda \int_{-a}^{a} k(x, y) \phi(y) d y=f(x) \tag{6}
\end{equation*}
$$

Then, write the integral term of (6) in the form

$$
\begin{equation*}
\int_{-a}^{a} k(|x-y|) \varphi(y) d y=\sum_{n=-N}^{N-1} \int_{n h}^{n h+h} k(|x-y|) \varphi(y) d y, \quad\left(h=\frac{2 a}{N}\right) \tag{7}
\end{equation*}
$$

Approximate the integral in the right hand side of Eq. (7) by

$$
\begin{equation*}
\int_{n h}^{n h+h} k(|x-y|) \phi(y) d y=A_{n}(x) \phi(n h)+B_{n}(x) \phi(n h+h)+R \tag{8}
\end{equation*}
$$

Where, $A_{n}(x)$ and $B_{n}(x)$ are two arbitrary functions will be determined and $R$ is the estimate error. Putting $\varphi(x)=1, x$ in Eq. (8) yields a set of two equations in terms of the two functions $A_{n}(x)$ and $B_{n}(x)$, where in this choosing we have $R=0$. By solving the results, the functions $A_{n}(x)$ and $B_{n}(x)$ will take the forms

$$
\begin{equation*}
A_{n}(x)=\frac{1}{h}[(n h+h) I(x)-J(x)], B_{n}(x)=\frac{1}{h}[J(x)-n h I(x)], \tag{9}
\end{equation*}
$$

The values of $I(x)$ and $J(x)$ are

$$
\begin{equation*}
I(x)=\int_{n h}^{n h+h} k(|x-y|) d y, \quad J(x)=\int_{n h}^{n h+h} y k(|x-y|) d y \tag{10}
\end{equation*}
$$

Hence, the relation (7), becomes

$$
\begin{equation*}
\int_{-a}^{a} k(|x-y|) \phi(y) d y=\sum_{n--N}^{N} D_{n}(x) \phi(n h) \tag{11}
\end{equation*}
$$

Where

$$
D_{n}(x)= \begin{cases}A_{-N}(x), & n=-N \\ A_{n}(x)+B_{n-1}(x), & -N<n<N \\ B_{N-1}(x), & n=N\end{cases}
$$

The integral equation (6), after putting $x=m h$, becomes

$$
\begin{equation*}
\phi(m h)-\lambda a_{n, m} \phi(n h)=f(m h) \tag{12}
\end{equation*}
$$

The function $\phi$ represents a vector consists of $2 \mathrm{~N}+1$ element. While, $a_{n, m}$ is a matrix whose elements are given by
$a_{n, m}=a_{n, m}^{\prime}+g_{n, m}, \quad a_{n, m}^{\prime}=A_{n}(m h)+B_{n-1}(m h), \quad-N \leq n \leq N$
The matrix $a_{n, m}^{\prime}$ is called the Toeplitz matrix of order $2 N+1$, where $-N \leq m, n \leq N$, and the elements of the second matrix are zeros except the elements of the first and last rows. We can evaluate the values of the first row by substituting in $B_{n-1}(m h)$, by $n=-N, m=-N+i, 0 \leq i \leq 2 n$, and
the values of the last row by substituting in $A_{n}(m h), b y \quad n=N, m=-N+i$.
The TMM is said to be convergent of order $r$ in $[-a, a]$, if for $N$ sufficiently large, there exist a constant $D>0$ independent of $N$ such that
$\left\|\phi(x)-\phi_{N}(x)\right\| \leq D N^{-r}$
The error term $R$ is determined from the following formula
$R=\left|\int_{n h}^{\mid n h+h} y^{2} k(|x-y|) d y-A_{n}(x)(n h)^{2}-B_{n}(x)(n h+h)^{2}\right|=O\left(h^{3}\right)$

## 4. Applications

Example 1:
Consider the integral equation:
$\varphi(x, t)=f(x, t)+\lambda \int_{-1}^{1} k|x-y| \varphi(y, t) d y+\lambda \int_{0}^{t} \tau^{2} \varphi(x, \tau) d \tau$

$$
\begin{equation*}
(0 \leq t \leq T ;|x| \leq 1) \tag{15}
\end{equation*}
$$

Where the exact solution when the kernel takes the logarithmic kernel and Carleman function is $\varphi(x, t)=x^{2}+t^{2}$. The tables (1-3) contain the numerical results of the example 1 according to different values of time.

Table (6)

## Conclusion

From the above results we note that:

1. When the function is symmetric with respect to $x$, the approximate solution by TMM also symmetric to sixth decimal.
2. The error function take one form in ТММ which maximum at the ends when $x=-1$, and $x=1$ and minimum at the middle when $x=0$ special when $n=21$.
3. As the time increases the error increases, while, as N increases the error decreases.
4. The stability of the TMM is better to evaluate the approximate solution than the product Nyström method, where the TMM and the product Nyström method are considered as the
best two numerical methods to solve the singular integral equation numerically, see $[9,10,14,15]$.
