Abstract: Organochlorine (OCPs) and organophosphorus (OPs) pesticides measured in water, sediment and fish samples along River Nile (the outfall of drain into River Nile) and its branches (Damietta and Rosetta,) that receive runoffs from agricultural lands and industrial pesticides. The study aimed to investigate the toxic waste status in the environmental matrices using biological biomarker, included fish and algae. Qualitative and quantitative analysis of OCPs and Ops during winter closure period (December 2013 – March 2014) were carried out using developing analytical method. Due to possible toxicity and bioaccumulation tendency of the OCPs and OPs in fish, the levels of OCPs and OPs must be detected in the fish samples that could be health problems source in the future. The obtained data depicted the varieties toxic measurements that showed significant differences of OCPs and OPs concentration and algae capacities in water. The OCPs and OPs detected are consistent with the agricultural activities of the study area due to pesticide usage and industrial pesticides. The levels of OCPs and OPs in the studied area were still within safety margins compared to the permissible limits for water and sediment. The study clarified biomarkers included fish and quality of algae communities valuable tool in bio-monitoring pollution for toxic pollution in ecological monitoring.

Key words: Ecological Monitoring, Fish, Sediment, Algae, Pesticides, River Nile

1. Introduction

River Nile is the principal freshwater resource for Egypt, meeting nearly all demands for drinking water, irrigation, industry and others. Human activities, agricultural and pesticides industry resulted a large range of toxic contaminants into aquatic ecosystems and caused negative effects in the environment.

The combined toxicity of pesticides pollution is complex that gives large range of toxic molecules (pesticides and their metabolites) in streams and other water bodies. The monitoring system of pesticides based on quantitative indicators that focused on monitor pesticide concentrations into different environmental matrices (water, sediment and biota) physical according to their and chemical characteristics (Cruz et al., 2014). They are rapidly absorbed and accumulated by the bottom sediment, plankton, algae, aquatic invertebrates, aquatic vegetation, fish and threat to the health and productivity of aquatic ecosystems (Ogunfowokan1 et al., 2012).

The application of OPs and OCPs increased output of agricultural products and better life quality. OCPs are known to be harmful for human health and the environment due to their persistence, bioaccumulative nature and high lipid solubility. These factors led to the problems of bio-concentration, biomagnification in biota tissues and they "biomagnify" up the food chain **(SEI, 2010)**. One such group of organochlorine pesticides has been classified as Persistent Organic Pollutants (POPs) **(UNEP, 2010)**.

OPs cause environmental problems when present at high concentration due to their highly soluble in water. They depend on their rapid degradation, depending on their formulation, method of application, climate and growing stage of plant (Abou El-Ella, 2007 and Ramzy and Abd El-Gawad, 2012).

The greatest potential of chance adverse effects of pesticides is the contamination of hydraulic system; hence water is primary responsible matrix to transport pesticides from the application area to other locations and pesticide contamination of ground water is a global issue (Ló pez-Blanco *et al.*, 2005 and Abd El-Gawad, 2008).

Biological markers define and measure the effects of presence organic pollutants on aquatic system. Various aquatic organisms occur in rivers, lakes, seas and marines potentially useful as biomarkers of organic pollutants including fish, aquatic plants and algae (**Rashed, 2001b**). The principle of biomarker approach is the analysis of fish to measure their pesticides contents in order to monitor pesticides excess in their tissues. Algae are excellent biological markers of pesticides in water to

define health and water quality status along River Nile and their sediment (Rashed, 2001a).

Skillful water control of environmental and public health problems in Egypt is required to overcome devastating effects on the ecological balance of the aquatic environment and the diversity of aquatic organisms. This paper focuses on the quantitative detection of 18 organochlorine pesticides including six different POPs (HCB, O, P'– DDT, DDD, 4, 4'-DDT, and α -HCH and β -HCH) and δ -HCH in water samples from River Nile around agricultural fields. The study conducted to evaluate the pesticide residues of OCPs and OPs in fish, sediment and water from River Nile (the outfall of drain into River Nile) and its branches along agricultural fields.

2. Materials and Methods

2.1 Area Description Environmental sampling is

Environmental sampling is carried out during winter closure period, (Dec.2012 – March 2013). The area of focused on Ten locations along River Nile (the outfall of drain into River Nile) namely Aswan, Qena, El-Menia, Helwan, Shoubra, Delta Barrage. Two drains outfalls are El-Rahway and industrial pesticide of Kafr El-Zayat pesticides Production Company along Rosetta branch. Additionally, two locations of River Nile along Damietta branch at 1096 and 1180 Km from Aswan represented many activities (Fig.1)

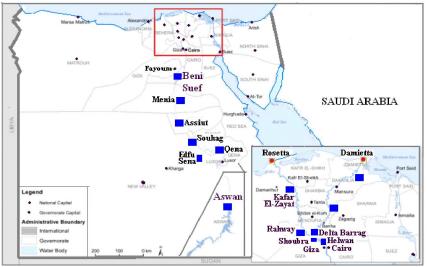

Fig.1 Study Location along River Nile and Nile Delta

2.2 Sampling

2.2.1 Water Samples

Water samples are collected directly from River Nile and its branches (Table 1) into pre-cleaned brown glass bottles (1 liter) in an ice box. Care was taken not to disturb the surface of the soil layer while collecting the samples.

Table	(1): Environme	ntal Sampling
-------	----------------	---------------

Sampling Site at R	iver Nile	Code		
Location	Distance (KM) from Aswan	Water	Sediment	Fish
Aswan	10	R1	S1	F1
Qena	280	R2	S2	F2
El-Menia	685	R3	S3	F3
Helwan	902 - Industrial and high population	R4	S4	F4
Shoubra	938 - Industrial and high population	R5	S5	F5
Delta Barrage		DP	DPS	DPF
El-Rahway drain	Rosetta branch- 962- outlet drain	RB6	RBS6	RBF6
Kafr El-Zayat	Rosetta branch- 1156-outlet pesticides production	RB7	RBS7	RBF7
Damietta branch	1180– many activities	DB8	DBS8	DBF8
Damietta branch	1096 - many activities	DB9	DBS9	DBF9

The water samples were not filtered to separate suspended particles because the suspended particles, especially fat particles, could contain POPs in them. Samples were kept in ice box for quick transportation and below 4°C until analysis. The concentration of OCPs and OPs evaluated according to international guidelines (Table 2).

2.2.2 Bed Sediment

Sediment samples are collected from depths (0 - 25cm) using pre-cleaned stainless steel sediment sampler from the selective sites. Samples are taken in plastic bags and delivered immediately to the laboratory. The samples are air dried at room temperature (25°C), crushed and finely ground, sieved through (0.2 mm) sieve. The concentration of OCPs and OPs evaluated according to international guidelines (Table 3).

2.2.3 Fish

A total of 50 individual adult fishes, Nile Tilapia (*Oreochromis niloticus*) were collected from the studying locations and kept in ice boxes during transportation. The collected samples were transferred quickly to the laboratory and immediately dissected .Muscles tissues were removed then kept at-4°C till analysis within few days to monitor the toxic residues during the investigated study. The concentration of OCPs and OPs evaluated according to international guidelines (Table 4).

2.2.4 Algae

Various characteristics of algae production including species and diversity reflect the ecosystem conditions for water quality and organic pollution levels. Algae as bio-indicators were sampled by dipping a plastic container into the water and collecting 1 L for each point. All samples were preserved in 4% neutralized formalin solution and their volumes were adjusted to 50ml in the laboratory by settling and removing the supernatant (Abd ElGawad and Hammad, 2011). In case of phytoplankton samples identification, 30 L were filtered through 20 μ m net mesh and fixed with Lugol's solution (APHA, 2012).

Sub-samples were filtered (Whatman GF/C membranes) and used to quantify chlorophyll-a using spectrophotometer DR-2010 - after acetone extraction (Golterman *et al.*, 1978). Algae identification were carried out by Sedwgwish Rafter counting method (APHA, 2012) using an Olympus binocular compound microscope. Determination of phytoplankton diversity and density were expressed on organism/liter Cell/L, respectively.

2.3 Extraction Procedure

2.3.1 Reagents:

The pesticide standards were purchased from Sigma-Aldrich with the purity of 99.8%. All other chemicals, solvents and reagents used in this study were of analytical grade. De-ionized water and free organic were used throughout the study.

2.3.2 Extraction of Residues - Water

A volume of 500 ml of each water sample was taken in a separating funnel and 50g of sodium chloride was added. The content was extracted three times with 50 mL of n-hexane. 30 g of anhydrous sodium sulphate was added to the combined extracts **(EPA, 1992)**. The extracts were filtered and the water-free organic layer was taken in an evaporation flask. The volume was carefully reduced to about 0.5 - 1.0 mL by evaporation. The sample was cleaned up with 2 mL of 95 - 97% pure sulphuric acid saturated with cyclohexane. The mixture was left for separation and the upper phase was taken for analysis in a gas chromatograph.

2.3.3 Extraction of Residues - Bed sediment

Extraction of organochlorine pesticide residues from bed sediment samples procedure, as described by **EPA**, **1986** was used. Air-dried bed sediment (10 gm) with 25gm anhydrous sodium sulphate is taken to the extraction cell. Extract the vessel with a mixture of hexane and acetone (10:3). When the extraction is complete transfer the contents into separatory funnel with adding 200 ml of free organic water. Samples extracts are combined and concentrated by rotary evaporating to approximately 5 ml, add 50 ml of nhexane and concentrate extract to approximately 2 ml (Leyva – cardoso *et al.*, **2003**).

2.3.4 Extraction of Residues - Fish

Ten grams of fish muscles were homogenized with 20 g of anhydrous sodium sulfate with tissue homogenizer till a fine homogenate was obtained. The homogenate was extracted with 50 ml of n-hexane: acetone (2:1) using HPLC grade. Extraction was carried out using orbital shaker for 2 hours, and then the extract was filtered through anhydrous sodium sulfate and evaporated till dryness, using rotary evaporator under vacuum at 40 °C. Blank trials for water, sediment and fish samples were carried out to remove any interfering materials coming from solvents used (Mosaad *et al.*, 2008).

2.3.5 Cleaning up of Sediment and Fish Samples

Cleaning up was carried out using 6g activated florisi (60-100 mesh) topped with 1 g anhydrous Na_2SO_4 then column was wet using 30 ml n-hexane then elution of sample was done with 200 ml of the following mixture dichloromethane : n-hexane: acetonitrile (50:48. 5:1.5) (Mills *et al.*, 1972).

2.4 Analytical Procedure

Organochlorine pesticide residues are measured bv subjecting samples to Finnigan Gas Chromatography (Hewlett Packard GC Model 6890), equipped with an Electron Capture Detector (ECD), The gas chromatograph condition: DB-17 capillary column (30m length x 0.32 mm internal diameter (i.d.) x 0.25 um film thickness). Operating temperatures: column temperature was programmed: initial oven temperature, 160 °C for 2 min., raised at 3° C/ min to 220 ° C, then raised 15 °C to 270 °C and then held at 240 °C for 15 min. Injector temperature was 280 °C and detector temperature 320 °C with nitrogen carrier gas flow at 4 m1/min. All compounds were identified by their retention times compared to known standards.

Peak areas were used as the basis for quantification. Standard solutions of OCPs including: Alfa-BHC, Gamma-BHC, Beta-BHC, Delta-BHC, Endrin Keton, Endrin, Endrin aldhyde, Dieldrin, chlorodan. Gamma Aldrin. Alfa chlorodan. Heptachlor, Heptachlor epoxid, Methoxychlor, Endosulfan I, Endosul fan II, Endosulfan sulfate, 4,4'-DDD, 4,4'-DDE, 4,4'-DDT were made from double distilled, deionized water. Each of the standards was

run thrice in the gas chromatograph to check whether the retention time was reproducible. After measuring the retention times of each standard, a mixture of standards was analyzed to verify whether all the retention times remained the same. In order to check the reliability of the experimental results, samples were spiked with 10 μ g/l of the mixed standards and the resultant peak areas were compared with the calculated values of the analytes. The concentration in samples was expressed in μ g/l.

Organophosphorus pesticide residues were determined by gas chromatograph, (Hewlett Packard GC. Model 6890) equipped with a flame photometric detector (FPD) with phosphorus filter. A fused silica capillary (DB-1701), column containing 14 % cyanopropilsyloxane as stationary phase (30 m length x 0.32 mm internal diameter (i.d.) x 0.25 μ m film thickness) was used for the separation in the GC.

The operating conditions of GC instrument included injector and detector temperature were 250 °C, initial oven temperature 175°C for 2 min, raised at 6°C/min., and then held at 240 °C for 15 min, the carrier gas nitrogen at 4 ml/min and hydrogen and

air were used for the combustion at 75 °C and 10 ml/min., respectively.

3. Results and Discussion

The obtained data depicted the concentrations of chlorinated pesticides residues included POPs and organophosphorus residues concentrations in environmental matrices (water, bed sediment) and biomarkers included fish and algae. The result clarified the release of applying chemical control and their effect on aquatic organisms that presented in Tables (5-7) and graphically illustrated in Figs. (2-5).

3.1 Qualitative and Quantitative Analysis3.1.1 OCPs in Surface Water

The data obtained from a broad study of 18 OCPs residue in water samples collected from environmental matrices along River Nile and its branches, drains outfall and industrial outfalls to detect the levels of organic contaminants and represent an challenge to advance our understanding of pollution in investigated sites as shown on Table (5) and valuable chromatogram of OCP residues in the standard sample is illustrated in Fig.(2).

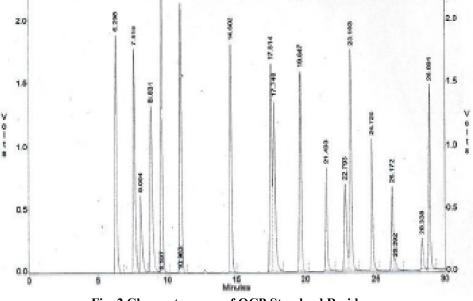

Fig. 2 Chromatograms of OCP Standard Residues

The obtained results revealed that the average levels of the detected organochlorine pesticide residues in investigated matrices were varied 7.9 to 95.4 μ g/l in water at Qena, El-Menia, Helwan, Shoubra, Kafr El-Zayat industrial pesticides, and Damietta branch. Aswan and Delta barrage recorded OCPs residue was < 0.01 μ g/l (minimum detection limits of the methods).

In all analyzed water samples, twelve OCPs are detected (below MDL $0.01 \mu g/l$), although they are

widely used in agricultural purposes. This can be attributed to the fast rate of degradation of this class of pesticides that was accelerated through the variation of climatic conditions in the study area. The obtained results agree with findings obtained by **Abd El-Gawad and Amer (2010)** and **Amer and Abd El-Gawad (2012)** in water of River Nile.

OCPs, especially DDT, were used intensively during past years; therefore, it is still detected with its metabolites (DDE and DDD) in irrigation, drainage canals and in low concentrations in the River Nile and its branches. This can be related to the currently flushing processes, its use during the past years, low rate of application and attachment to the sediments along their flow as they are associated with solid phase or due to its low solubility and low photooxidation. The HCHs concentrations was 12.21 μ g/l have lower values than DDTs' in water (Table 5) because of their differences in physico-chemical and biological properties, having HCHs a higher water solubility, vapor pressure, biodegradability, lower lipophilicity and particle affinity as compared to DDTs properties. The major component (77%) of the commercial DDT is the P,P' isomer. It can be speculated from the results that commercial DDT is being used in almost all the sample sites. DDD was found in 5 samples and their concentrations ranged from 25.33 to 95.4 μ g/l. P,P' DDE was found in Kafr El-Zayat industrial company and the concentrations was 15.33 μ g/l and 9.15 μ g/l for PP, DDT at El-Menia. Almost all the samples had at least one of the three isomers of DDT in them. The presence of these DDT isomers is an indication of the continued use of POPs in agriculture. The concentration of aldrin varied from 7.9 to 8.85 μ g/l while endrin concentration ranged from 73 to 29.3 μ g/l.

3.1.2 **OCPs in Sediment**

Pesticide leaching from the soil into drains, irrigation water and finally into the Nile and pose serious environmental and health risks. This depends on the type of pesticide, soil characteristics, hydrogeological conditions, climatic factors, agro-technical factors and human factors. The results of sediment sample analyses for the same study sites are shown in table (5). All the samples collected had at least one of the seven organochlorine pesticides present. No sample site showed the presence of all seven POPs pesticides, but Helwan sample (R4) showed the presence of six OCPs pesticides.

The minimum detection limits of the methods used for extraction of OCPs residue from bed sediment is 0.01 µg kg. In all analyzed bed sediment samples, OCPs are detected (below the method detection limit 0.01 µg/kg). In general, the levels of OCPs in sediment are still within safety margins compared to the permissible limits for Canadian sediment quality guidelines in Table (3) (Abdel Gwad and Rashed (2008)). Among the analyzed organochlorine residues in sediment samples, α BHC, β-BHC, Heptechlor, Aldrin, Hep. Eposide, Chlordane, pp-DDE Endrin, pp.DDD, and PP-DDT were detected at levels ranging from ND to 12.64 ng/g for α –BHC, 65 to 359 ng/g for β -BHC, 86.87 ng/g at R7 for y- BHC, 140 to 370 ng/g for Heptachlor, 36 to 300 ng/g for Heptachlor epoxide, 14 to 25 ng/g for Aldrin, 16 to 249 ng/g for Endrin, 7 to 275 ng/g for pp. DDD and 315 to 730 ng/g for pp. DDT and 55to 345 ng/g for γ -chlordane. Monitoring program recorded DDTs residues in all studied samples except Qena and Damietta branch while the highest detected level of DDTs was at Aswan Dam.

OCPs in Fish 3.1.3

Organochlorine pesticides levels of all investigated sites in fish were below permissible levels according international limits except heptachlor was 203.6 ng/g at Kafr El-Zayat industrial pesticides. OCPs pollution at Kafr El-Zavat (aldrin), Helwan (endrin) and Damietta (endrin) along water, sediment and fish was attributed to the continued pesticides industry and use chemical control for agricultural pests.

Although concentration of POPs in most of the samples were within the regulatory limits, it must be emphasized that POPs are inherently unmanageable and they bio-accumulate in living species. Therefore, the acceptable standard for any POP in any sample should ideally be zero (Li et al., 2006).

Organophosphorus Pesticide 3.2 in **Environmental Matrices**

3.2.1 **OPs in Water**

Concentrations of organophosphorus pesticides locations are shown in Table (6). in studied

Compounds identified included ethoprophos, diazinon, Chlorpyriphos methyl, chlorpyriphos, malathion, fenitrothion, fenthion, fenthioate, and profenophos. Tables (6) illustrate OP concentration in water samples for ten locations sites. The level of concentrations were 100 ng/l for Diazinon at Dommettia branch, 45 ng/l for Chlorpyriphos methyl at Kafr El-Zyat industrial pesticide company, 18 and 21 ng/l for fenthion at Helwan and Kafr El-Zyat industrial pesticide company, 24 ng/l for Fenthioate and 38 and 41ng/l for profenophes in Helwan and Kafr El-Zyat industrial pesticide company.

Ops in Bed Sediment 3.2.2

Residues of OPs in sediments is marked that the concentrations of studied compounds were subject to considerable variation with value to sites. Table (6) showed the concentration values were 59 and 155 ng/g for Chlorpyriphos methyl in El-Menia and Kafr El-Zvat industrial pesticide company and 37ng/g for fenthioate in El-Menia. The presence of chlorpyrifos methyl and fenthioate, in sediments samples could be attributed to the intense agricultural activity in the and industrial pesticides. area Most organophosphorus pesticides residues were non detected in water and sediment may be aspect to its rapid degradation, depending on their formulation, rate of application, method of application and climatic factors. These compounds are highly soluble in water and relatively short-lived in the environment.

3.2.1 **OPs in Fish**

In fish, bioaccumulation concentration (BC) from water through the gills, skin, and food is a possible route for organophosphorus (OP) pesticide to accumulate in tissue: the route depends mainly on their feeding preference, general behavior, and trophic level (Abd El-Gawad and Ramzy, 2013). The present study indicated OPs tendency for methyl 159.15 to 83.28 ng/g, Chlorpyriphos Chlorpyriphos 41.5 to 83.12 ng/g, Fenitrothion 100.8 212 ng/g, Fenthioate 45.2 to 109.6 and Profenophos 91.1 to 98.93 to bio-accumulate in Nile Tilapia (Oreochromis niloticus) while the other OPs were not detected (Table 6).

Biological Marker 3.3

In present investigation algal communities which are used as biomonitors of pesticides pollution in study area. Total 5 genera have been identified, among these 26 species belonged to Chlorophyceae, 25 species to Cyanophyceae and 20 species to Bacillariophyceae. Table (7) showed the list species of Chlorophyceae and the most pollution tolerant species of Oocystiselliptica (Hansgirg, Oocystisparva (Wittrock, Pediastrum simplex and Scenedesmusopoliensis. The obtained results agree with findings obtained by Abd El-Gawad and Ramzy, 2013.

Table (8) showed the list species of Cyanophyceae and the most pollution tolerant species of Anabaena fertilissimaForti, Anabaena spiroides, Aphanocapsaelachistavar.conferta and *Microcystisaeruginosa*Kutz.

Table (9) showed the list species of Dinophyceae and the most pollution tolerant species of *Peridiniumumbonatum* (Woloszynska).

Table (10) showed the list species of Bacilariophyceae and the most pollution tolerant CyclotellameneghinianaKutz, species of

CyclotellaocellataPant, Melosiragranulata(Her.) Ralfs, Melosiragranulata var. angustissima(Her.) Ralfs and SyndraactinstroidesKutz.

The algal communities indicate that Helwan and Kafr El-Zavat were highly organically polluted. Table 11 depicted the varieties percentage of algae communities, total OCPs and OPs concentrations in environmental matrices. The toxic waste affect on biomarker included fish and algae species distribution and their difference.

4. Conclusion

Ecological monitoring was carried out for toxic waste along River Nile and its branches included drains outfall and industrial outfalls and Delta Barrage as reference point during winter closure period (December 2013 – March 2014). The presented data indicated most of organochlorine pesticide and organophosphorus residues in surface

water, bed sediment and fish samples are found below the detection limit. $0.01 \ \mu g/l$, $0.01 \ ng/g$ and not detected for water, bed sediment and fish, respectively.

From the results, River Nile (the outfall of drain into River Nile) shows that the residues of organochlorine and organophosphorus pesticides exist in low concentrations in water, sediment and bio-accumulated in majority Nile Tilapia (*Oreochromis niloticus*). These residues have apparently originated from the areas of intensive pesticide application in Helwan and Kafr El-Zayt industrial pesticides company along River Nile and Rossetta branch.

The natural processes of weathering are likely to result in the transfer of pesticide residues from site to another to the main course of the Nile, especially during the rainy season and hence their transport downstream. Increased contamination with residues is certain to adversely affect the fish population and difference of algae communities for the development of the fish feeding in this vital area. In order to keep the situation under control, it is essential that a system for the continuous monitoring of residues as key environmental components in the whole River should be established.

Recommendations

• Continuous monitoring of pesticide residues to detect any probable addition of organochlorine pesticide along Nile.

• Study suitable enzymatic treatment for individual industry, specially Kafr El-Zayat and Helwan area.

Acknowledgement

The authors gratefully Acknowledgement their colleges in Central Laboratory for Environmental Quality Monitoring (CLEQM) and Channel Maintains Research Institute (CMRI) for their valuable cooperation, providing all facilities, suggestions and financial assistance.
